

# WHAT WE LEARNED FROM THE PORT

---

Eindhoven, 7-MAR-2023

**Camiel Vanderhoeven**

# About me

- ▶ The Netherlands, 1977, educated in Eindhoven
- ▶ VMS Kernel developer since 2015
  - ▶ Mode changes
  - ▶ 4 modes on a 2 mode architecture
  - ▶ Emulated VAX features
    - ▶ ASTs
    - ▶ Software Interrupts
    - ▶ Queue Instructions
  - ▶ Scheduler
  - ▶ POSIX threads
  - ▶ AMD CPU Support
- ▶ Computer collection: [www.vaxbarn.com](http://www.vaxbarn.com)

# Agenda

- ▶ Developing on Virtual Machines
- ▶ Masquerade
- ▶ Why probe?
- ▶ “Unified” Extensible Firmware Interface
- ▶ “Let’s be different!”

# Developing on Virtual Machines

- ▶ Quick to setup
- ▶ Quick to boot
- ▶ Snapshots, cloning
- ▶ Post-mortem

# Masquerade

- ▶ 4 modes
  - ▶ 4 pagetables per process
  - ▶ Complex code for transitioning between modes
- ▶ 8k pages
  - ▶ Native pages on x86 are 4k
  - ▶ VMS pages are 8k
  - ▶ Memory needed for UEFI may be in adjacent 4k pages
- ▶ Queue Instructions
- ▶ Probe Instructions

# Why Probe?

- ▶ System service calls
  - ▶ Verify caller has access
  - ▶ Avoid pagefaults at elevated IPL
- ▶ Interrupts / exceptions
  - ▶ Avoid pagefaults at elevated IPL
  - ▶ Invalid stack pointers
- ▶ **NO PROBE INSTRUCTION ON X86**
  - ▶ Walk the page tables “by hand”
  - ▶ Validate input parameters
  - ▶ ~ 900 instructions executed

# “Unified” Extensible Firmware Interface

Where we came from:

- ▶ Alpha

- ▶ Single vendor: Digital / Compaq / HP
- ▶ SRM
- ▶ Galaxy Configuration Tree

- ▶ Itanium

- ▶ Single vendor: HP / HPE
- ▶ Extensible Firmware Interface
- ▶ System Abstraction Layer / Processor Abstraction Layer hides

# “Unified” Extensible Firmware Interface

Where we ended up:

- ▶ X86-64
  - ▶ Multiple vendors / hypervisors
  - ▶ UEFI (without SAL or PAL)
  - ▶ ACPI (advanced Configuration and Power Interface)
- ▶ Every hypervisor is different
  - ▶ Sometimes even between versions of the same Hypervisor
- ▶ Bare-metal hardware is different again

# “Unified” Extensible Firmware Interface

# “let’s be different”

- ▶ VMware, VirtualBox, XEN, KVM
  - Have their differences, but ...
  - Virtual machines pretend to be real hardware
  - Provide emulated devices and controllers – SCSI, SATA, Intel NIC, Chipset
  - Can provide higher speed, lower latency virtualized I/O interfaces *if the OS asks to use them*
  - In short: are able to accommodate OS'es that know nothing about Virtual Machines

- ▶ Hyper-V

- Virtual machines are unapologetically virtual constructs
- Does not provide emulated devices or controllers
- Requires that the OS use virtualized I/O interfaces
- In short: requires the OS to know how to run on Hyper-V

A group of approximately 25 people are seated in a room, facing a large projection screen. The screen is currently blank. The room has a white door in the background and a speaker on the left. The people are dressed in casual business attire, and many are wearing lanyards with badges. The overall atmosphere is professional and focused on an interactive session.
